MediCloud

Centralizing Hospital Workflows & Patient Care

Full Case Study

Duration:
4 Weeks: UI/UX Design & Prototyping
6 Weeks: for Full-Stack Development & Deployment

Product Overview

MediPulse is a comprehensive B2B SaaS platform specifically designed for healthcare providers. It seamlessly integrates electronic health records (EHR), staff scheduling, and real-time bed management into a single, intuitive hub to boost clinical efficiency and reduce administrative burnout.

Responsibility

- UI/UX Design
- Web App Developer
- Testing & Launch

Tools

- Figma
- Figjam
- Node.js
- Tailwind CSS
- MongoDB
- Node.js

Problem Statement

Healthcare facilities frequently struggle with scattered workflows, relying on a fragmented ecosystem of legacy applications for patient records, staff scheduling, and billing. This constant context-switching leads to critical miscommunications, delayed triage times, and staff burnout.

Goals

Centralize core hospital operations into one unified dashboard. Reduce patient intake and triage time by at least 30%. Build a highly scalable, HIPAA-compliant web application architecture.

Development Process

The end-to-end product lifecycle for MediPulse seamlessly bridged human-centered design with robust full-stack development. We began by defining clinical pain points through targeted research, which drove the creation of an intuitive information architecture and high-fidelity Figma prototypes governed by a strict, accessible design system. For the engineering phase, we established a secure, scalable backend using Node.js and Express.js, leveraging MongoDB and Tailwind CSS for efficient, utility-driven styling. Finally, we engineered a scalable, HIPAA-compliant Node.js backend with RESTful APIs and strict Role-Based Access Control (RBAC), supported by an optimized relational database that instantly links patient EHR data to bed availability to power the real-time triage analytics dashboard.

Research & Discovery

To ensure MediCloud addressed real-world clinical bottlenecks, the user research phase utilized a mixed-methods approach centering healthcare professionals. We began by developing scenarios to filter out non-essential features, ensuring the platform was lean, efficient, and only included software tools. From there, we surveyed over 50 professionals to measure time lost to app-switching and conducted in-depth, 1-on-1 interviews with nurses, gathering qualitative observations, which revealed deep-seated frustrations regarding siloed patient data, inefficient bed management, and the inability to clearly track staff capacity. These empirical insights formed the direct foundation of our persona and empathy maps.

Observations

80%

of clinical managers struggle to access unified patient histories quickly during triage.

80%

find staff shift scheduling chaotic across different

50%

spend excessive time manually calling departments to check bed availability.

Pain Points

1. **Workflow Fragmentation**
   Constant context-switching between specialized EHR tools and isolated scheduling software delays patient care.
2. **Data Silos**
   Legacy systems trap real-time bed and clinical resource availability due to decentralized tracking.
3. **Blind Spots**
   A critical lack of automated reporting forces staff to spend off-hours compiling compliance and capacity reports.

User Research

o ensure MediPulse solved actual clinical bottlenecks rather than just administrative ones, we conducted a mixed-methods research phase targeting over 50 hospital administrators, head nurses, and ER triage staff. Quantitative surveys revealed that 80% of clinical staff struggle to access unified patient histories quickly during triage, and 50% spend excessive time manually calling departments to check bed availability. This data was heavily supplemented by qualitative user interviews, which highlighted deep-seated frustrations with clunky legacy EHR systems that prioritize billing features over direct patient care and cause severe cognitive fatigue. Ultimately, these empirical insights formed the foundation of our user personas and empathy maps, driving our decision to focus the dashboard experience on real-time bed management, instant staff communication, and reducing cognitive load in high-stress environments.

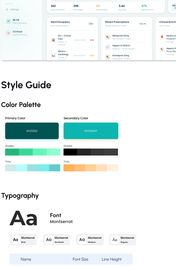
Unique Features

- Unified Bed Management: Links real-time patient discharges directly to global bed availability statuses to optimize intake flow.
- Role-Based Health Records: Secure, HIPAA-compliant EHR access where permissions are automatically inherited from the staff member's specific medical role and ward assignment.
- Cross-Functional Triage Analytics: Cross-references patient wait times with current staff capacity to predict bottlenecks and dynamically adjust triage protocols.
- Unified Clinical Log: Tracks administrative updates, staff handovers, and critical patient treatment milestones in a single, transparent feed.

Target Audience

Chief Medical Officers | Head Nurses | ER Triage Directors | Hospital Administrators

Empathy Map



Says
"I waste critical time switching between different systems to see a patient's history."
"We don't have real-time visibility into which available beds right now."
"Who has the authority to schedule for the ICU wing?"
"We need a faster way to update patient statuses during peak ER hours."
Thinks
"There must be a better way than to have a nurse call a doctor's office."
"I can't afford a mistake because of a miscommunication when lives are on the line."
"I hope the new float pool system doesn't cause more confusion for this week."
"A centralized dashboard would help us so much administrative stress for my team."
Does
Manually calls different wards to verify bed availability and transfer of medical supplies.
Closes down physical paper charts when the shift ends to allow for data entry.
Spends overtime hours catching up on documentation and digital training and compliance reporting.
Feels
Overwhelmed by disjointed, outdated healthcare software that slows them down.
Frustrated when administrative bottlenecks delay urgent patient care.
Anxious about data privacy and HIPAA compliance during security, and emergency access.
Exhausted by the endless clicks that takes time away from focused patient interaction.

Key Takeaways

Designing for healthcare required a hyper-focus on reducing visual clutter. In a high-stakes ER environment, minimizing click fatigue and clearly surfacing critical data (like severe allergies) is just as important as strict HIPAA compliance. Establishing a strict, token-based design system in Figma dramatically accelerated the frontend React build and ensured a consistent, accessible experience across the entire platform.

Roadmap

Version 2 of TeamHub will focus on expanding interoperability by introducing third-party API integrations (Slack, Google Workspace) and implementing automated, AI-driven productivity insights to help managers
